4. Conclusion

# 1. Introduction

Recently H. Georgi proposed a model of unparticles. The main speculation : suppose there is conformal invariant world (gauge theory with fermions with ultraviolet fixed point as an example). For such conformal world all 2-point functions  $\langle O(p)O(-p) \rangle$  behave like  $D(p^2) \sim (p^2)^{2\beta+2d-3}$  , where  $\beta$  is anomalous dimension of the operator  $O$  and  $d$  its naive dimension. As a consequence there is no single particle pole in the spectrum . The spectrum is continuous.

The main support of the possible existence of 4-dimensional conformal models is due to the fact that for some number of matter fields in gauge models one-loop beta function contribution is negative while two-loop correction is positive that leads to speculation about existence of fixed point

For instance for QCD with  $n_f$  flavours

$$\beta(\alpha_s) = -\beta_0 \alpha_s^2 (2\pi)^{-1} - \beta_1 \alpha_s^3 (2\pi)^{-3} + O(\alpha_s^5)$$

$$\beta_0 = 11 - 2n_f/3; \quad \beta_1 = 51 - 19n_f/3$$

For  $8 < n_f < 16$  in PT we have fixed point.

Suppose conformal “unparticle world” and our world are connected due to nonrenormalizable interaction

$$L_i = c\Lambda^{-n}O(\text{particle})O(\text{unparticle})$$

Due to assumed interactions two types of observable effects are possible:

a. Production of unparticles at colliders :

$$qq \rightarrow qU$$

$$gg \rightarrow gU$$

Unparticles being weakly interacting in our world are not detected and behave like neutrino

As a consequence we obtain that unparticles signature are events with missing transverse momentum and hadronic jet(s) like in ADD model which describes our 4 dimensional world plus gravity in  $(4 + n)$  dimensional world with compactification of  $n$  additional dimensions (tower of massive gravitons).

b. Exchange of unparticles leads to additional propagators

$$D(p^2) \sim (p^2)^{-\Delta}$$

that change the SM predictions for cross sections like  $DY$ ,  $\gamma\gamma$  production, ...

***In other words:***

- ***Due to assumed interactions of particles and unparticles it is possible to produce unparticles in particle collisions .***
- ***As a consequence of continuous spectrum of unparticles and weak interactions with particles unparticles are not detected . How to detect unparticles?***

***1. Missing Transverse Energy***

***2. Unparticle exchange leads to the modification of particle propagators. So study of processes like dimuon production allows to constrain particle-unparticle interactions***

***Some unparticle references:***

***1.H.Georgi, Phys.Rev.Lett. 98 221601(1997).***

***Plus a lot of “unparticle exercises” , for instance:***

***2. K.Cheung et al, Collider Phenomenolgy of Unparticle Physics, arXiv:07063155***

In this talk I show that the notion of an unparticle can be described as a particular case of a field with continuously distributed mass. I also review the models with continuously distributed masses and describe possible phenomenological implications for Large Hadron Collider(LHC)

This talk is based on my papers:

1. N.V.K., Higgs boson with continuously distributed mass, Phys.Lett. B325(1994)430.
2. N.V.K., Unparticle as a field with continuously distributed mass, Int.J.Mod.Phys. 22 (2007) 5117.
3. N.V.K., LHC signatures for  $Z'$  models with continuously distributed mass, Mod.Phys.Lett. 23 (2008) 3233.

Also I have to mention related work

## 2. Fields with continuously distributed mass

Let us start with  $N$  free scalar fields  $\Phi_k(x_k)$  with masses  $m_k$ . For the field

$$\Phi(x_k, m_k, c_k) = \sum c_j \Phi_j(x_j, m_j)$$

free propagator has the form

$$D_{\text{int}}(k^2) = \sum |c_j|^2 (k^2 - m_j^2 + i\varepsilon)^{-1} = \int \rho(t, c_j, m_j) (k^2 - t + i\varepsilon)^{-1} dt, \\ \rho(t, c_j, m_j) = \sum |c_j|^2 \delta(t - m_j^2),$$

n2

In the limit  $N \rightarrow \infty$ ,

$$\rho(t, c_j, m_j) \rightarrow \rho(t) \text{ and} \\ D_{\text{int}}(k^2) \rightarrow \int \rho(t) (k^2 - t - i\varepsilon)^{-1} dt$$

For instance for

$$m_k^2 = m^2 + k\Delta N^{-1} \text{ and } |c_k|^2 = N^{-1} \text{ in the limit } N \rightarrow \infty \\ \rho(t) = \theta(t - m^2) \theta(m^2 + \Delta - t) \Delta^{-1}$$

For spectral density  $\rho(t) \sim t^{\delta-1}$  the propagator

$$D_{\text{int}}(k^2) \sim (k^2)^{\delta-1}$$

that corresponds to the case of unparticle propagator and the limiting field  $\Phi(x, \rho(t)) = \lim_{N \rightarrow \infty} \Phi(x, m_j, c_j)$  describes unparticle field. It is possible to introduce self interaction in standard way as

$$L_{\text{int}} = -\lambda(\Phi(x, \rho(t)))^4$$

For finite  $\int \rho(t) dt$  the asymptotics of the effective propagator coincides with free propagator

$D(p) \sim (p^2)^{-1}$  and the model is renormalizable.

The generalization to the case of vector fields is straightforward. Consider the Stueckelberg Lagrangian

$$L = \sum_k [(-1/4) F_{\mu\nu, k} F^{\mu\nu, k} + (1/2) m_k^2 (A_{\mu, k} - \partial_\mu \Phi_k)^2]$$

Gauge invariance:

$$A_{\mu, k} \rightarrow A_{\mu, k} + \partial_\mu \alpha_k,$$

$$\Phi_k \rightarrow \Phi_k + \alpha_k$$

For the field  $B_\mu = \sum c_k A_{\mu,k}$  in the limit

$N \rightarrow \infty$  we obtain free unparticle vector field for power like spectral density

One can introduce gauge invariant interaction with fermion field  $\psi$  in standard way

$$L_{\text{int}} = e \psi \gamma_\mu \psi B_\mu$$

For such model Feynman rules the same as in QED except the change photon propagator  $1/k^2 \rightarrow D_{\text{int}}(k^2)$ .

Another approach to the fields with continuously distributed mass related with

the introduction of additional space dimensions.

The main peculiarity is that we postulate Poincare invariance only in 4-dimensional space-time but not Poincare invariance in  $(4+n)$ -dimensional space-time.

Consider scalar field  $\Phi(x_\mu, x_4)$  in five-dimensional field interacting with the four-dimensional fermion field  $\psi(x)$ .

krasnikov; 29.06.2009

The scalar action has the form

$$S_1 = (1/2) \int [\partial_\mu \Phi \partial^\mu \Phi - \Phi f(-\partial_4^2) \Phi] d^5x$$

This action is invariant only under 4-dimensional Poincare group and 5-dimensional free propagator is

$$D_0 = (k_\mu k^\mu - f(k_4^2))^{-1}$$

The interaction of 5-dimensional scalar field with 4-dimensional fermion field is

$$L_{\text{int}} = g \psi(x_\mu) \psi(x_\mu) \Phi(x_\mu, x_4 = 0)$$

One can say that fermion field lives on 4-dimensional brane while scalar field lives in 5-dimensional world.

- For such interaction Feynman rules the standard as for 4-dimensional model except the use of effective scalar propagator

$$D^{\text{eff}}(k^2) = (2\pi)^{-1} \int [k^2 - f(k^2_4) + i\epsilon]^{-1} dk_4$$

One of possible generalizations to the gauge fields is to consider Yang-Mills in 4-dimensional space-time with standard action and matter fields in 5-dimensional space-time with the replacement of

the mass  $m^2 \rightarrow f(-\partial_4^2)$ . So for such kind of models gauge field  $A_\mu^a(x)$  lives on four-dimensional brane, while matter field lives in 5-dimensional dimensional space-time and the Poincare invariance holds only in 4-dimensional space-time.

$$S_F = \int d^5x [ \psi (i\gamma^\mu \partial_\mu + gT^a A^a_\mu \gamma^\mu - m(-\partial^2_4)) \psi ]$$

Feynman rules for such model coincide with standard except the use of fermion propagator

$$i[\gamma^\mu p_\mu - m(p^2_4)]^{-1} \text{ and additional}$$

integration  $(2\pi)^{-1} dp_4$  in fermion loop. For

the case when  $m(p^2_4) = 0$  for  $|p_4| < \varepsilon\pi$  and

$m(p^2_4) = \infty$  for  $|p_4| > \varepsilon\pi$  the single difference

between our model and 4-dimensional case is

additional factor  $\varepsilon$  for each fermion loop due to additional integration over  $dp_4$  in

fermion loop so the model is renormalizable and one loop  $\beta$ -function is

$$\beta(g) = -g^3(11N/3 - 2\varepsilon/3)/16\pi^2 + O(g^5)$$

# Phenomenological implications

There are a lot of possible extensions of Standard Model with continuously distributed Higgs boson mass. For instance, consider SM in the unitary gauge and make replacement in free Higgs boson propagator

$$(p^2 - m_H^2)^{-1} \rightarrow D_{\text{int}}(p^2) = \int \rho(t) [p^2 - t + i\varepsilon]^{-1} dt$$

For  $D_{\text{int}}(p^2) = (p^2 - m_H^2 + i\Gamma_{\text{int}} m_H)^{-1}$  we can interpret  $\Gamma_{\text{int}}$  as internal Higgs boson decay width into 5-th dimension.

For large  $\Gamma_{\text{int}} \gg \Gamma_{\text{tot,H}}$  we shall have additional suppression factor

$$\Gamma_{\text{tot,H}} (\Gamma_{\text{tot,H}} + \Gamma_{\text{int}})^{-1}$$

for standard signatures like  $pp \rightarrow H + \dots \rightarrow \gamma\gamma + \dots$

to be used at the LHC that can make the LHC Higgs boson discovery practically impossible.

# Phenomenological implications

For  $D_{\text{int}}(p^2) = \sum |c_n|^2 (p^2 - m_n^2 + i\varepsilon)^{-1}$  and  
for  $(m_k - m_{k-1})$  bigger than detector resolution we  
shall have several peaks  
in the reactions

$$pp \rightarrow \gamma\gamma + \dots$$

$$pp \rightarrow ZZ^* + \dots \rightarrow 4l + \dots$$

to be used for Higgs boson search at the  
LHC with factor  $|c_n|^2$  suppression for each  
resonance that for big  $n$  makes the Higgs boson  
discovery at LHC extremely difficult or even  
impossible

# Phenomenological implications

- It should be stressed that the proposed generalization of the SM model is renormalizable if the ultraviolet asymptotics of the Higgs boson propagator  $D_{\text{int}}(p^2)$  coincides with free propagator

$$D_0(p^2) = (p^2)^{-1}$$

# Phenomenological implications

Another possible implications are models of  $Z'$  bosons with continuously distributed mass. Most models predict the existence of new narrow vector boson  $Z'$  with

Total decay width  $\Gamma_{\text{tot}} = O(10^{-2})M_{Z'}$ , while in model with continuously distributed  $Z'$  boson mass  $Z'$  boson could be very broad and possible consequence is the existence of broad structure for dimuon mass distribution in the reaction

# Conclusions

1. Unparticles can be interpreted as fields with continuously distributed mass.
2. Fields with continuously distributed mass can be treated as fields in  $d > 4$  space-time and from experimental point of view it is not necessary to require Poincare group in  $D$ -dimensional space-time (only 4-dimensional Poincare group follow from experiment)
3. Renormalizable extensions at  $d > 4$  are possible.
4. There are possible testable at the LHC phenomenological consequences like Higgs boson or  $Z'$  boson decaying into additional dimension(s)
